How can Oil and Gas prevent disease emergence and improve worker and community health?

USAID and its partner projects have developed and are testing tools to help governments and extractive industries identify ways to evaluate potential exposure points where vulnerabilities or risks of transmission exist and mitigation measures. These tools include a Planning Tool, an Audit Tool, and an educational program. The following graphic depicts how these tools fit into a project’s life cycle.

The tools include best management practices to prevent disease transmission. The following are key measures that can be implemented:

- **Minimize wildlife disturbance and contact**
  - Limit habitat fragmentation by reducing footprint size and numbers of roads and corridors constructed
  - Develop an inventory, regularly monitor the local fauna, take action to prevent loss of diversity
  - Prohibit onsite hunting

- **Use good housekeeping measures at the facility and any camps and canteens**
  - Maintain clean working and living facilities
  - Ensure clean, protected water sources and good sanitation
  - Establish management procedures to prevent disease transmission to domestic animals
  - Build/retrofit facilities (with special attention to food storage) to exclude rodents, bats, and other pest/scavengers
  - Use standard public health measures for sanitation and food handling

- **Monitor and improve employee health**
  - Ensure employees are properly vaccinated
  - Conduct surveillance for any unusual diseases
  - Conduct health promotion campaigns about infectious diseases
  - Assist local government to engage in community planning, especially in designing waste management services
  - Conduct health promotion campaigns about infectious diseases, bushmeat, sanitation, etc.
  - Engage community leaders and other stakeholders in discussions about safe methods to hunt bushmeat, expand communities, develop infrastructure, etc.
  - Ensure workers can access affordable protein
  - Provide sources of protein for workforce to reduce the potential for bushmeat hunting and consumption

The planning and audit tools are available at [http://preventproject.org](http://preventproject.org). You can also contact USAID/Extractive Industry Working Group at mitigatep@gmail.com

Why should Oil and Gas be concerned about emerging infectious diseases?

Emerging infectious diseases occur in “hot spot” areas throughout the world where Oil and Gas operations occur. Emerging infectious disease can affect industry by:

- Causing outbreaks or illness, resulting in productivity losses
- Requiring quarantines that could close or suspend operations
- Killing employees or community members, contributing to systems breakdown, damage to corporate image, and possible project closure

Oil and Gas can address emerging infectious diseases

Environmental and social changes affect how people, pets, livestock, and wildlife interact and can create conditions that favor the emergence and spread of infectious diseases, such as Lassa fever, Marburg fever, Ebola, and SARS. Most emerging diseases are zoonotic, transmitted between animals and humans. By understanding how to minimize the risk of zoonotic disease transmission, Oil and Gas companies can safeguard worker and community health.

**IMPORTANT FACTS:**

- Oil and Gas operations can change interactions between people, domestic animals, and wildlife in ways that lead to conditions favorable for disease emergence.
- Nearly 75 percent of emerging infectious diseases are zoonotic (originate in animals).
- Incorporating an evaluation of zoonotic disease risk factors in Environmental, Social, and Health Impact Assessment protocols can help identify disease emergence risks and point to prevention and mitigation options.
- The Oil and Gas industry can adopt best management practices to mitigate the risks of zoonotic disease emergence and improve worker and community health.

This publication was made possible through the support provided by the United States Agency for International Development (USAID). The opinions expressed herein are those of the author(s) and do not necessarily reflect the views of the US Agency for International Development or the US Government.
What wildlife transmit zoonotic diseases?

Nearly three-quarters of emerging infectious diseases originate from wildlife. Three wild animal groups, which comprise approximately 70 percent of mammal species, are considered most likely to spread new infections to people: bats (coronavirus responsible for Marburg, and rabies viruses), rodents (Lassa, hanta, and monkeypox viruses) and non-human primates (Ebola and yellow fever viruses). People contract these diseases by inhaling aerosolized contaminated feces and urine, through direct contact via scratches, bites, and bodily fluids—such as blood and saliva—that can occur during hunting and food preparation, and by ingesting contaminated food, water, or undercooked meat. The following table lists some viruses, animals, and transmission routes.

### Virus

#### Animal

- Lassa Virus: Rodents (Lassa, hanta, and monkeypox viruses)
- Lake Victoria Marburg Virus: Monkeys
- Ebola Zaire Virus: Primates
- Marburg Virus: Primates
- Rabies Virus: Rodents
- Yellow Fever Virus: Monkeys

#### Common Transmission Routes

- Lassa Virus: Contaminated food and water—most common; direct animal contact (consumption or bite); inhalation of aerosols.
- Lake Victoria Marburg Virus: Direct contact with the blood, body fluids, or tissues of an infected animal or person; prolonged close contact with an infected person.
- Ebola Zaire Virus: Direct contact with the blood, body fluids, and tissues of an infected animal or person; prolonged close contact with an infected person.
- Marburg Virus: Transmission occurs through the bite and virus-containing saliva of an infected host. Aerosol transmission is suspected.
- Rabies Virus: Transmission occurs through the bite and virus-containing saliva of an infected host.
- Yellow Fever Virus: Transmission occurs through the bite and virus-containing saliva of an infected host. Aerosol transmission is suspected.

### How do Oil and Gas activities affect the risk of zoonotic disease transmission?

Oil and Gas requires a large labor force for construction. Others follow the workers to seek jobs or establish businesses to serve the area’s new population. Such project-induced migration can increase the likelihood of disease transmission.

- Strains on existing housing and infrastructure can lead to overcrowding, poor sanitary conditions, improper storage of waste, and insufficient potable water. These conditions create habitats and food sources that attract pests—including insects and wildlife—carrying diseases that can be transmitted to people.
- The growing population creates pressure for agricultural expansion into previously undeveloped areas.
- Demand for meat may lead to increased numbers of domestic animals and increased hunting and marketing of wild meat.

All these factors exacerbate the potential risk of “spillover” by increasing contact between people, domestic animals, and wildlife populations. This can increase the likelihood of cross-species disease transmission. The following figure depicts some of the mechanisms that can increase contact between people, wildlife, and domestic animals.

---

### Ebola and Marburg Outbreaks Near Mines in Africa

In 1995, an Ebola outbreak occurred in M’bikoko and other gold-mining camps deep in the rain forest of Gabon. The mortality rate was 60 percent. The 1998-2000 Marburg outbreak in DRC proved fatal to 128 of 154 cases, representing a case fatality of 83 percent. From June to August 2007, three confirmed cases of Marburg were reported in mineworkers from Kamwenge, western Uganda. One caregiver died, and the mine was closed for more than a year.

How the Oil and Gas Industry Can Address Emerging Infectious Diseases

How can Oil and Gas prevent disease emergence and improve worker and community health?

USAID and its partner projects have developed and are testing tools to help governments and extractive industries identify ways to evaluate potential exposure points where vulnerabilities or risks of transmission exist and mitigation measures. These tools include a Planning Tool, an Audit Tool, and an educational program. The following graphic depicts how these tools fit into a project’s life cycle.

Integrating EID Tools into the Extractive Industry Project Cycle

The tools include best management practices to prevent disease transmission. The following are some key measures that can be implemented:

**Minimize wildlife disturbance and contact**
- Limit habitat fragmentation by reducing footprint size and numbers of roads and corridors constructed
- Develop an inventory, regularly monitor the local fauna, take action to prevent loss of diversity
- Prohibit onsite hunting

**Use good housekeeping measures at the facility and any camps and canteens**
- Maintain clean working and living facilities
- Ensure clean, protected water sources and good sanitation
- Establish management procedures to prevent disease transmission to domestic animals
- Build/retrofit facilities (with special attention to food storage) to exclude rodents, bats, and other pest/scavengers
- Use standard public health measures for sanitation and food handling
- Discourage waste accumulation and dispose of waste regularly and properly to deter wildlife
- Reduce/eliminate exposed standing water to remove potential vector breeding sites

**Monitor and improve employee health**
- Ensure employees are properly vaccinated
- Conduct surveillance for any unusual diseases
- Conduct health promotion campaigns about infectious diseases
- Assist local government to engage in community planning, especially in designing waste management services
- Conduct health promotion campaigns about infectious diseases, bushmeat, sanitation, etc.
- Engage community leaders and other stakeholders in discussions about safe methods to hunt bushmeat, expand communities, develop infrastructure, etc.
- Ensure workers can access affordable protein
- Provide sources of protein for workforce to reduce the potential for bushmeat hunting and consumption

Oil and Gas can address emerging infectious diseases

Environmental and social changes affect how people, pets, livestock, and wildlife interact and can create conditions that favor the emergence and spread of infectious diseases, such as Lassa fever, Marburg fever, Ebola, and SARS. Most emerging diseases are zoonotic, transmitted between animals and humans. By understanding how to minimize the risk of zoonotic disease transmission, Oil and Gas companies can safeguard worker and community health.

**Why should Oil and Gas be concerned about emerging infectious diseases?**

Emerging infectious diseases are a growing concern for Oil and Gas industries due to:
- Potential economic losses from productivity disruptions
- Risk of reputational damage and public backlash
- Contribution to workforce safety and health
- Impact on local communities

**Oil and Gas can address emerging infectious diseases**

By implementing best management practices and integrating EID tools, Oil and Gas can mitigate the risks of zoonotic disease emergence and improve worker and community health.

**IMPORTANT FACTS:**

- Oil and Gas operations can change interactions between people, domestic animals, and wildlife in ways that lead to conditions favorable for disease emergence.
- Nearly 75 percent of emerging infectious diseases are zoonotic (originate in animals).
